Efficacy of endoscopic sinus surgery for paranasal sinus mucocele including modified endoscopic Lothrop procedure for frontal sinus mucocele

Abstract
This study evaluated the efficacy of the modified endoscopic Lothrop procedure (MELP) for complicated frontal mucoceles and endoscopic marsupialization for other paranasal sinus mucoceles.

It was a retrospective, consecutive case review of sinus mucoceles treated endoscopically by a single surgeon over a four-year period (1998–2002).

There were 41 mucoceles in 28 patients, including 24 frontal, eight frontoethmoidal, three ethmoidal, five maxillary and one frontal mucocele. Twenty-one patients underwent the modified Lothrop procedure for frontal mucoceles, and seven underwent simple drainage and marsupialization for frontoethmoidal, ethmoidal and maxillary mucoceles. At median follow-up of 16 months, all patients had a patent mucocele opening. Patients treated by drainage and marsupialization did not have any complications or mucocele recurrence. All patients treated by the modified endoscopic Lothrop procedure had improvement in symptoms and signs. Four patients had minor complications including epistaxis and adhesions and five required further surgery. The average hospital in-patient stay was 2 ± 1.4 days.

Endoscopic techniques, including MELP are effective in the short term for the management of complex and simple paranasal sinus mucoceles. MELP has a useful place in the management of mucoceles with a significant bony partition from an adjacent sinus or nasal cavity. It is also indicated when the mucocele is associated with loss of lateral support in the sinus with risk of medial-wall collapse of the orbital contents obstructing drainage.

Key words: Mucocele; Frontal sinus; Endoscopy; Surgical Procedures, Operative; Paranasal Sinus Disease

Introduction
Over the past decade, intranasal drainage and marsupialization of mucoceles using endoscopic sinus surgery has emerged as definitive management, with minimal morbidity and a low recurrence rate. Two clinical situations remain a challenge. The first is where there is significant bony separation between the mucocele and the rest of the sinuses or nasal cavity and the mucocele is not bulging into an adjacent sinus or nasal cavity. After marsupialization a circumferential raw area of bone will remain between the mucocele and the sinus or nasal cavity. Due to the circumferential nature of the injury, the opening tends to stenose and the mucocele may recur. The second problem is when the mucocele erodes the floor and/or posterior wall of the frontal sinus. In this situation the mucocele lining is adherent to the orbital periosteum or the dura. Removal of the lining may be difficult if obliteration of the mucocele is intended and recurrences may occur.

The aim of this paper is to evaluate the efficacy of endoscopic sinus surgery for performing drainage and marsupialization for paranasal sinus mucocele and the efficacy of the modified endoscopic Lothrop procedure (MELP) for complicated frontal sinus mucoceles that have a significant bony separation from the nasal cavity and sinuses, and for those mucoceles that have eroded the bone of the orbit or dura.

Materials and methods
This was a retrospective, consecutive case series of all paranasal sinus mucoceles undergoing endoscopic sinus surgery at the Department of Surgery-Otolaryngology and Ophthalmology, Adelaide and Flinders Universities, over a four-year period between 1998 and 2002. A single surgeon (PJW) performed all surgery. Surgical procedures included endoscopic sinus surgery drainage and marsupialization for

352
uncomplicated paranasal sinus mucoceles (n = 7) and MELP for complicated frontal sinus mucoceles (n = 21). Intra-operative image guidance (Landmarkx, Medtronic Xomed, Jacksonville, FL, USA) was used in all the MELP procedures and for two of the endoscopic sinus surgery cases.

A mucocele was defined as an expansion of an existing sinus with associated erosion of septations within the sinus and the walls of the sinus. Only patients who fulfilled this criterion were included.

Patient profile data consisted of demographic details, past history of sinus surgery, concurrent naso-laryngopharyngeal comorbidities, the mucocele site and pre-operative findings on computerized tomography (CT) and in some patients magnetic resonance imaging (MRI).

All patients underwent a clinical evaluation. Pre- and post-operative features including ocular and nasal symptoms were charted. The initial management and follow-up was also recorded. Outcome measures included change in symptoms and signs, patency of the mucocele opening, mucocele recurrence, complications, additional surgery required and duration of hospital stay.

Data were recorded on an Excel spreadsheet. Continuous data were analysed using the t-test and described as mean and standard deviation (mean ± SD).

Results and analysis
Twenty-eight patients (17 males and 11 females) with 41 paranasal sinus mucoceles underwent endoscopic sinus surgery. The mean age was 52 ± 16.6 (range 15–83) years. The median follow-up was 16 months (range 1–42 months).

Sites included frontal (61 per cent), frontoethmoidal (20 per cent), ethmoidal (seven per cent) and maxillary (12 per cent) sinuses. Eight (29 per cent) of patients had multiple mucoceles. Twenty-one (75 per cent) of cases were managed with MELP while seven (25 per cent) of cases required only endoscopic sinus surgery for the management of their mucoceles. Of the 21 cases that underwent MELP, four required concurrent endoscopic sinus surgery. The technique of MELP is described elsewhere.

Patients' symptoms and signs were summarized and categorized, according to the procedure they underwent, into the endoscopic sinus surgery and MELP subgroups (Table I). Frontal pain (57.1 per cent), nasal obstruction (57.1 per cent) and rhinorhoea (42.9 per cent) were the main presenting symptoms in the endoscopic sinus surgery subgroup as compared to frontal pain (71.4 per cent), headache (52.4 per cent), nasal obstruction (38.1 per cent) and posterior nasal drip (38.1 per cent) in the MELP subgroup. Two patients from the endoscopic sinus surgery subgroup and one from the MELP subgroup had a palpable mass on presentation. Medial canthus masses were correlated with the presence of frontoethmoidal mucoceles and gingivolabial sulcus swelling was associated with a left maxillary mucocele. One case with a frontal mucocele presented with progressive reduction of vision to 6/18, ptosis and periorbital swelling as a result of orbital cellulitis complicated by preseptal abscess. His visual acuity returned to 6/6 within two weeks of the MELP procedure.

In the endoscopic sinus surgery patient group, none had significant separation of their mucoceles from the nasal cavity or the sinuses on imaging. Most patients had extension of the mucocele into the orbit (71 per cent) and nearly half (43 per cent) had globe displacement. Two patients had erosion of the medial orbital wall and the orbital roof. In the MELP patient group, 10 (48 per cent) had orbital extension and eight (38 per cent) had globe displacement. Eleven (52 per cent) patients had a thick bony wall separating the mucocele from the sinuses and the nasal cavity. Two of the frontal sinus mucoceles were located laterally (Figure 1(a)) and two were located superiorly in the frontal sinus. Erosion of the orbital wall and skull base was present in 10 (48 per cent) patients (Figure 1(b) and 1(c)). These included four patients with dehiscence of the posterior table of the frontal sinus, six with orbital roof erosion, two with erosion of the medial orbital wall, one with erosion of the lamina papyracea and three with intracranial extension (Table II).

Prior ENT history and co-morbidities are summarized in Table III.

Treatment outcome
All patients treated by endoscopic sinus surgery alone had a patent sinus ostia. None required additional surgery. One had minor epistaxis after the procedure.

Priors: 1. ESS group includes patients who underwent only endoscopic sinus surgery. 2. MELP group includes patients who underwent both endoscopic sinus surgery and MELP. 3. Symptoms and signs are presented as percentages of the total number of patients in each group.
In the MELP group, two patients had stenosis of their frontal ostium requiring revision surgery to re-establish a widely patent frontal ostium. These frontal ostia have subsequently remained patent and the patients asymptomatic. One patient needed toileting of the frontal ostium at one month to clear crusts and debris from the marsupialized mucocele ostium. Self-limiting complications were recorded in three cases in the MELP patient group. These were minor epistaxis, adhesions between the middle turbinate and lateral nasal wall and adhesions between the middle turbinate and septum.

Nine patients, (five from the MELP group and four from the endoscopic sinus surgery group) had incomplete resolution of symptoms. Their nasal symptoms were attributable to ongoing nasal and sinus pathology including chronic fungal sinusitis and recurrent nasal polyps. Residual symptoms include headache, rhinorrhea, nasal obstructions, frontal pain and posterior nasal drip.

The median duration of in-patient stay was two (mean 2 ± 1.4, range one to six) days. Twelve patients were managed as day cases and six patients stayed overnight after the procedure. Those that remained as in-patients for longer did so for non-medical reasons (patients lived too far for immediate out-patient follow up).

**Discussion**

Mucoceles are expansile masses originating in the sinuses usually presenting with frontal headache, nasal obstruction and eye signs such as globe displacement, diplopia, proptosis, lid swelling, palpable mass and at times reduced vision and ptosis.

Scarring of the sinus opening is the most common cause for mucocele formation. The frontal and ethmoidal sinuses were the most commonly involved, which reflects the predisposition for their small sinus openings to be damaged during sinus surgery or trauma, or by repeated infections with subsequent obstruction and mucocele formation. Most patients (93 per cent) in our series had prior sinus surgery (86 per cent), chronic sinusitis (79 per cent) or trauma (seven per cent).

Endoscopic management of mucoceles protruding into the other sinuses or nasal cavity has been the accepted treatment for years. Our results confirm the success of treating uncomplicated mucoceles with standard endoscopic sinus surgery techniques. However, mucoceles presenting with a significant bony separation from the other sinuses or nasal cavity are more complex and difficult to manage. This bony divide needs to be removed by a drill so that a large enough opening is created into the mucocele that will stay patent in the long term. In this series MELP provided short-term successful management of these complex patients.

The alternative to drilling away this bone is to approach the mucocele via external incisions, remove its entire lining and obliterate it with fat. A survey of contemporary practices in the United Kingdom showed that while many surgeons routinely performed endoscopic sinus surgery, 54 per cent...
of surgeons would still rely on the external approach for frontal sinus mucocele and pyocele.\textsuperscript{12} However, if the mucocele has eroded the orbital roof or skull base and there is extensive apposition of mucocele mucosa on the orbital periosteum or dura, complete removal of the mucocele is very difficult. If mucosa remains and the sinus is obliterated then recurrence of the mucocele is likely.\textsuperscript{7} The follow-up of an obliterated sinus can also be unreliable as imaging may not be able to distinguish an obliterated sinus from a recurrent mucocele.\textsuperscript{12} In addition, it has been shown that the mucosa of a mucocele do not lose normal respiratory epithelium\textsuperscript{13,14} and follow-up endoscopic examination has also found well-mucosalized cavities after mucocele marsupialization.\textsuperscript{4} These findings suggest that there is no added benefit in attempting to remove the mucocele lining if it is closely applied to either the orbital periosteum or dura.

MELP provides the largest possible access to the frontal sinuses\textsuperscript{5,15} and allows muceceles based in the lateral regions of the frontal sinuses to be accessed and opened as widely as possible. This wide access improves the potential success rate of maintaining a patent opening into the mucocele.

This study showed that MELP was used successfully to open 11 muceceles separated from the nasal cavity and sinuses and 10 muceceles with significant erosion of either the orbital roof or skull base. Two patients required revisions due to mucocele recurrences but all currently have patent ottia. While the authors acknowledge that the follow-up period is still relatively short, MELP has proved to be a reliable alternative for the management of difficult and complex muceceles of the frontal sinuses. MELP has a useful place in the management of muceceles separated from the nasal and sinus cavity by a thick bony divide. In addition MELP is also indicated when the mucocele is associated with loss of lateral support in the sinus with risk of medial-wall collapse of the orbital contents obstructing drainage. These recommendations augment those of previous authors that most paranasal sinus muceceles can be successfully managed by endoscopic marsupialization into the nasal cavity.\textsuperscript{16,17}

This study adds to the number of publications advocating endoscopic sinus surgery as a safe and effective approach for mucocele management.\textsuperscript{3,8,16,17} Har et al.\textsuperscript{9} reported the largest series of 103 patients (108 muceceles) with a median follow-up of 4.7 years and a recurrence rate of 0.9 per cent. This also represents the longest follow up for endoscopically managed muceceles. However, significantly longer follow up is necessary to fully evaluate outcomes. Recurrence of mucocele after osteoplastic and obliteration procedures was 19 per cent (nine out

- This paper evaluates the outcome from a modified endoscopic Lothrop procedure for frontal sinus and marsupialization for other paranasal sinus muceceles in 28 patients.
- At 16 months follow up all patients had adequate drainage of their muceceles.
- Four patients, all of whom had Lothrop procedures, had minor complications.
- The paper concludes that endoscopic procedures for paranasal sinus muceceles are effective in the short to medium term.

</table>
of 47 patients) in a retrospective study\textsuperscript{18} whereas in
two endoscopic series,\textsuperscript{1,2} the recurrence rate was
zero per cent with minimal complications. It is
important to note that in the latter two studies, patients thought not suitable for an entirely endo-
cscopic approach due to complex sinus anatomy were
managed with an external approach or a combined
endoscopic and external approach. However, despite
the addition of an external incision, the principle of
mucocle marsupialization into the nasal cavity was
maintained and obliteration was rarely performed.

In conclusion, MELP should be considered as an
alternative to external obliteration for the treatment
of complex frontal mucocles. Endoscopic marspu-
rialization should be considered the first line
treatment for simple paranasal sinus mucocles.
