Conflicts of interest: The author declares no conflict of interest.

Authors' contribution: KM, SB, DM and GM were responsible for the literature review area of focus and question. With the assistance of KM, SB & DM, GM was responsible for identifying search terms, conducting literature searches and carrying out the analysis of papers and the preparation of the manuscript. KM, SB and DM contributed to all areas of the process and were heavily involved in the editing and final preparation of the review.

**Purpose:** Food banks have become the main response to food insecurity in many high-income countries, but it has been argued that they lack the capacity to respond consistently and fully to the food needs of the people who use them. This literature review set out to answer the question ‘how do food bank recipients experience food relief services and how does this impact their lives and wellbeing?’

**Results:** A comprehensive search of electronic databases yielded twenty qualitative studies, conducted in developed countries, exploring user perspectives of food banks. From the studies reviewed, there emerged three main categories that represented the different aspects of the food bank process from the food bank user’s perspective: the user’s perceptions about the idea of being fed from food banks, the user’s perceptions about food bank offerings and operations, and the socio-psychological impact of receiving food from food banks. While participants of these studies spoke positively of the volunteers and were thankful for the service, they also consistently report limited food choice, poor quality, shame, stigma and embarrassment associated with food bank use.

**Conclusions:** The food bank industry continues to expand despite there being little evidence that food banks are an appropriate response for those facing food insecurity. This is worrying as the results of this review indicate that although participants value the service provided by the food bank, the experience can be largely negative. These findings raise questions about the food bank model as a long-term strategy.
Introduction

Food insecurity occurs “when people do not have adequate physical, social or economic access to food”\(^1\). While food insecurity is most commonly associated with the developing world, food shortage and deprivation are also a problem in many high-income countries, that appears to be getting worse\(^2\).

Food banks have now become the dominant response to food insecurity in many of these high-income countries (including Canada, the United Kingdom, the United States of America and Australia)\(^3,4\). Food banks can generally be described as non-profit organisations that collect, store and distribute donated and surplus food to hungry people, either directly or by going through front line social welfare agencies\(^3\). Operationally food banks may differ, for example some operate in large warehouses, others are small local community service centres or church-run agencies\(^3\). Some food banks rely solely on donations from individuals in the community and industry oversupply, have little control over the items they receive, and are therefore limited in what they can offer to those in need\(^2\), while others also buy food when their stocks are running low\(^3\). They can provide food to individuals in the community in two main ways; providing pre-packaged hampers that have been made up by the food bank staff, or allowing recipients to choose food items from a pseudo-supermarket set up. Along with providing food, some food banks undertake advocacy work, referring to other agencies and providing education programmes\(^3\). Although the operational logistics may differ among the food banks, the basic premise remains the same, namely to provide food charity to those in need.

The number of food banks has been growing since the 1980’s. In the UK, between the years 2010 and 2012, the number of food banks increased from 54 to 201, a 372% increase.\(^4\) Australia has also seen an expansion from one food bank in New South Wales in 1992 to at least one food bank in every state and territory by 2010\(^5\). An increase in food bank services has also been seen in Canada\(^6\) and the United States of America\(^7\). This growth and expansion of food banks as a surplus food response to food insecurity, speaks to both the inadequacy of social policy to meet the basic needs of households, and the failure of governments to adequately address the underlying structural causes of food insecurity\(^3,8\). As Riches (2011) has asked “are charitable food banks symptoms and symbols not only of broken social safety nets but also of failing food and income redistribution policies?”\(^9(p5)\). The growth and reliance of food banks to meet the need of those facing food insecurity is concerning, as several studies suggest they offer little more than a ‘band-aid’ response to poverty and perpetuate over-production in the food system\(^2,3\). As food banks are becoming the
dominant response to food insecurity, they are the focus of this paper, rather than other charitable food organisations such as soup kitchens and co-ops.

It has been argued that food banks lack the capacity to respond consistently and fully to the food needs of the many people who use them\(^2\),\(^{10}\),\(^{11}\). There is speculation that food banks may actually contribute to the problem of food insecurity, rather than solve it, by allowing governments to ‘look the other way’, transferring the responsibility of food insecurity onto these charitable institutions, rather than fixing the social conditions that allow it to prevail\(^2\),\(^4\),\(^5\),\(^9\).

Several studies have found that most food bank users are young (mean age ranging from 25.5-46.3 years), have low paid, sporadic employment or are unemployed, and experience some degree of food insecurity\(^12\),\(^10\),\(^13\),\(^14\). While these studies help paint a picture of who the ‘typical’ food bank user might be, there are few papers that investigate how the people who use food banks feel about the experience. This scoping review investigates the perceptions and experiences of food bank users documented in research undertaken in the last 15 years, and the effect these services may have on their lives and wellbeing. We attempt to answer the question ‘how do food bank recipients experience food relief services and how does this impact their lives and wellbeing?’

**Methods**

A comprehensive systematic search was conducted using electronic databases including Web of Science, Medline, Scopus and PsycINFO on 17\(^{th}\) August 2015. Due to the paucity of literature found, the grey literature was also searched on Theses Canada, Australian National University, New Zealand Research, DART Europe, Ethos UK, Social Care Online, Find it @ Flinders, New York Academy of Medicine, Informit, Trove and by hand-searching organisations for reports, such as Foodbank Australia, Feeding America Research, Foodbanks Canada, Anglicare Australia and Trussell Trust Research. The specific search terms used in these searches included a combination of key words such as ‘food bank’, ‘foodbank’, ‘food pantry’, ‘food assistance’, ‘satisfaction’, ‘experience’, ‘opinion’ and ‘attitude’. The lack of consistency between search terms used for each database has its justification in the limited scope and reach of some of the smaller databases used, compared with the larger databases which allow for a more specific search. Hand searching of reference lists and citing articles was conducted in order to identify any other relevant studies and ensure the widest scope of literature possible. Due to the lack of literature in this area, all publications were included regardless of the year in which they were published. The search method can be seen below in Figure 1.
Key Words
Food bank, foodbank, food pantry, food assistance, satisfaction, opinion, experience, attitude

Grey Literature Searched
Theses Canada, NZ research, ETHOS UK, DART Europe, Social Care Online, NY Academy of Medicine, Australian National University, Informit, Trove, Find it @ Flinders, Anglicare network, Trussell Trust Foundation, Feeding America, Foodbank Australia

Excluded: n = 12
- Quantitative study, n = 5
- Food bank user perspectives on food insecurity only, n = 2
- Didn’t gather data from users = 2
- Descriptive characteristics only, n = 1
- Didn’t specifically look at food banks, n = 2

Included: n = 16
- Hand searching reference lists and citing articles, n = 4

Total number of articles included in review: n = 20
Grey Literature: n = 11
Peer reviewed: n = 9

Figure 1: Flow diagram of search methods
This review was limited to qualitative studies or those that used both quantitative and qualitative methods. Qualitative methods are useful for answering ‘how’ and ‘why’ questions and they are able to explore the experiences of individuals, something which quantitative methods are not able to do\textsuperscript{15, 16}.

Although there were studies conducted in high-income countries other than those included in this review, many could not be included as they were not accessible in English. As listed in the inclusion criteria below in Table 1, only studies published in English were included.

Other charitable food services are available such as food co-ops, soup kitchens and food stamp programs, however this review focused only on food banks. The inclusion and exclusion criteria are summarised in Table 1.

Table 1: Inclusion and exclusion criteria for literature searches.

The Critical Appraisal Skills Programme (CASP) Qualitative Checklist was used to assess the quality of the 20 studies included in the review. It was chosen because it has been validated and widely used in published assessments of qualitative studies\textsuperscript{17}. CASP Qualitative Checklist contains 10 questions, with prompts to consider that help researchers to critically appraise qualitative studies\textsuperscript{18}. Each question requires a “yes”, “no” or “can’t tell” answer, which the prompts help to guide. As there was a paucity of literature in this area, studies were included even if they did not meet “yes” for all questions. The possible consequences of including studies that did not meet all criteria in this review are explored below in the discussion.
One author (GM) was responsible for conducting the search and reviewing the literature, with assistance and input from other members of the team (KM, SB, DM). The process involved first screening of the titles and the abstracts of the papers. If the articles seemed to meet the inclusion criteria they were then read in full. From here only the articles that met the inclusion criteria after being read in full were included in this review. Once the final articles had been selected, they were read closely in order to identify the key findings, processes, underlying assumptions and knowledge gaps. A meta-ethnographic synthesis of the papers was undertaken, where the key findings, themes and concepts across the different studies were analysed and grouped together to form the themes for this paper. These themes found across the studies represent the different aspects of the food bank process from the user’s perspective. The themes identified from the literature were: user perceptions about the idea of being fed from food banks, user perceptions about food bank offerings and operations, and socio-psychological impact of receiving food from food bank.

**Article Selection Process**

A total of 20 studies met all search criteria, sourced from scientific databases, grey literature databases and hand searching.

**Findings**

**Summary of studies**

The 20 papers included in this review are all empirical studies that collected some form of qualitative data from individuals who had received food assistance from food banks. Seven studies used one qualitative method, six studies used more than one qualitative method, five used a mix of qualitative and quantitative methods, and two studies used multiple qualitative methods along with quantitative methods. The range of qualitative methods used can be seen below in Table 2.

**Table 2. Qualitative methods used in the studies to gather information regarding user perception of food banks.**

The details of each study can be seen below in Table 3. The studies included ranged from published literature \(^4, 10, 21, 27, 29-31, 33, 34, 36, 37\), to theses \(^20, 22-26, 28\) and organisation reports \(^32, 35\) and were published between 1999 and 2015. Most were conducted in Canada \(^10, 20-24, 29\), followed by the United Kingdom (UK) \(^4, 32-35\), the United States of America (USA) \(^27, 30, 36, 37\), New Zealand \(^25, 28\) and the Netherlands \(^26, 31\). There were no Australian studies found that met the criteria for this review. Two of the studies looked at food banks in rural settings, one in Canada and the other in the USA \(^21, 27\), the remaining focused on food banks located in urban settings.

Four studies examined and recruited participants from one particular food bank, Lethbridge Canada \(^20\), the Netherlands \(^31\), North East England \(^33\) and North East Scotland \(^34\), while the remaining 16 focused on multiple facilities \(^4, 10, 21-30, 32, 35-37\). The description of the specific food service used was not provided by all studies, but based on the studies that did provide the information, it was clear that the vast majority of services were providing pre-packaged parcels \(^4, 20-26, 28, 30-34, 36, 37\), with some providing choice of extra items \(^10, 23, 36, 37\), and one where individuals could select their own food items \(^34\).

The user perspectives fell into three main categories in the literature: user perceptions about the idea of being fed from food banks, user perceptions about food bank offerings and operations and socio-psychological impact of receiving food from food bank.

1. User perceptions about the idea of being fed from food banks

A recurring theme expressed by a number of participants in these studies was that food bank use was a last resort, and only when absolutely necessary \(^22-25, 27-29, 32, 34\). Hicks-Stratton (2004) found that participants felt ‘forced’ to use the food bank because of the situation they were in, and use was as a result of desperation \(^24\). Commonly participants were reluctant to use food banks as they viewed it as ‘unnatural’ \(^32\), stating that it challenged their pride and made them feel inadequate as providers for their families, causing feelings of embarrassment and shame \(^20, 23, 28, 32\). However, regardless of these feelings, participants continued to use food banks because they needed the assistance \(^23, 24\).

Some participants in these studies had come to rely on the food bank, stating that they would not know what they would do without the food provided from these facilities \(^21, 37\). In this way, food banks were sometimes viewed as a “lifeline” \(^33, 34\), something that prevented users from resorting to other more drastic, sometimes illegal strategies to obtain food \(^33, 34\). Participants in both De Marco (2009) and McNeill (2011) described food bank as a “godsend”, meaning they felt “blessed” that this service was available to them \(^27, 28\). In some cases, food bank use helped ease stress, especially
financially, as it allowed them to save the money they were not spending on food to go towards other necessities. Participants in both Douglas et al. (2015) and Perry et al. (2014) viewed food bank use as a turning point; it gave them hope, helped alleviate an immediate food crisis and in some cases was a way back into work if they were able to volunteer at the facility. Nikou (2002) found that food bank users that were able to volunteer felt they were giving back to the community, not just relying on a handout, which increased their comfort in using these services.

Not all participants viewed their food bank use in a positive way. A number of respondents were openly concerned about their reliance on the food bank and the service it provided. Across the studies, participants suggested that they never thought they would have to resort to using food banks, they disliked asking for help, and their continued reliance on food banks bothered them. For some, having to depend on the food bank was “oppressive and unpleasant”, however, they continued using the food bank oftentimes because they needed it to feed their children. Knowing that using the food bank meant that their children were fed made the process easier, however some participants still described an inner struggle every time they went to the food bank.

2. User perceptions about food bank offerings and operations

2.1 User perceptions about the food bank operations and services

Participants expressed both positive and negative comments about the food banks they used, regarding both the service and food provided. The majority of positive comments attributed to food banks were about the volunteers. Participants stated that the volunteers were often friendly, non-judgemental and supportive, and treated users with dignity, anonymity and respect.

A number of food bank users appreciated the opportunity to connect with other people in similar situations at the food bank, valued the social contact and found it a supportive environment where they could develop friendships and support networks. Garthwaite et al. (2015) found that the food bank encouraged a sense of community that helped ease the feelings of stigma and shame that were often experienced.

2.2 User perceptions about the food quality

Many comments about the food received from food bank were negative. Participants described dissatisfaction with both the quality and quantity of the food provided. Due to limited food choice, participants had to take food that they would not regularly eat, did not know how to...
prepare or was inappropriate in terms of cultural or health needs. Participants questioned the quality of the foods provided at the food bank, stating that it was often “unhealthy”, “expired”, “mouldy”, “rotten”, “disgusting”, “doesn’t look edible” and “not fit to feed an animal”. Sub-optimal food quality caused stress and anxiety and could impact on participants feelings of self-worth. However there were also a number of participants who stated, “beggars can’t be choosers”, indicating their resignation and loss of control over their situation.

3. Socio-psychological impact of receiving food from food bank

3.1 Emotional impact

Shame, embarrassment, degradation, humiliation, awkwardness, failure, desolation, intimidation, guilt, discomfort, powerlessness, inequity, nervousness and frustration, were all expressed by participants in relation to having to use the food bank. These feelings were particularly apparent leading up to the first use of the food bank, and at times would prevent participants from using the services, even though they needed the assistance. A number of respondents felt that food bank use had a negative impact on their identity, self-esteem, reputation and dignity.

Nevertheless, the majority of participants stated that over time they came to accept their use of food bank, and were able to put aside their ‘emotional entanglements’, however some felt that the experience never got any easier. There were some participants who recognised their need for the help and therefore did not experience these negative emotions at all.

Another emotion that was discussed by participants was gratitude. Van der Horst et al. (2014) found that many participants felt that they were expected to feel gratitude towards the services, and that they only expressed gratitude because they knew it was expected of them. Hicks-Stratton (2004) found that some participants were not willing to display gratitude for something that they were dissatisfied with; they took a stand and returned food to the food bank due to poor quality which helped restore some pride and self-respect.

3.2 Social impact

Shame and embarrassment were common experiences noted by study participants. They discussed fear of being seen at the food bank, fear of being judged and fear of social stigma. They felt that ‘begging’ for food or receiving ‘charity’ would create a negative social image and were embarrassed by how others might view them, which in turn often led to secrecy about food bank use and in some instances prevented people from using them.
Although participants were afraid of being stigmatised and stereotyped as a ‘food bank user’, they themselves had preconceived ideas of what a typical ‘food bank user’ was. There were perceptions that food banks were for the homeless, welfare recipients and the unemployed. Due to these perceptions, some participants were uncertain of whether they qualified to receive assistance from the food bank, as they perceived others as more ‘needy’ than themselves. This perception that food banks were for the ‘needy’ could make it hard for participants to accept help, as they were not used to asking for assistance, and disliked having to do so. The fear of stigmatisation was interesting, as it led some users to develop a hierarchy that distinguished themselves from the stereotypical, ‘non-deserving’ users. They discussed stereotypes, labelling some food bank users as lazy and unable to manage their finances, and tended to separate themselves from these types of food bank users.

To examine the role of emergency food in the lives of Latino/a immigrants in Seattle, Washington.

Ethnographic fieldwork and semi-structured interviews with agency representatives, and 46 first-generation immigrants from various regions of Latin America. Data was analysed systemically.

Emergency food services were far greater than participants could access in their home countries. Some hesitancy to use food banks, even if use was viewed as potentially beneficial. Mostly positive feelings about food bank, some comments about food not meeting cultural or culinary preferences or needs.

Emergency food programs in this area have a significant impact on the rates of food insecurity and hunger of Latino/a immigrants and others. The emergency food system is ill equipped to maximize community self-reliance and social justice.

To address how food, social status and the interactions at the food bank induce emotions in receivers, such as shame, gratitude and anger.

Participant observation and qualitative in-depth interviews with 4 food bank referrers, 5 food bank volunteers and 17 food bank receivers. Transcripts were analysed using Atlas.ti using open coding.

Receivers didn’t feel taken seriously, some indicating feelings of loss of self-worth, embarrassment and shame in receiving the parcel, interacting with volunteers and interpreting their place in society. Receivers felt they were expected to feel gratitude and satisfaction with parcels.

Shame and gratitude were prominent emotions linked to the food parcel and interactions with the volunteers. Most clients did not see food bank as a...

Discussion

This review set out to answer the question ‘how do food bank recipients experience food relief services and how does this impact their lives and wellbeing?’ Through a scoping review of qualitative studies, using a range of investigative methods to explore the user perspectives on food banks, we were able to bring together and present a broad overview of the perceptions and experiences of these individuals, and have captured the various ways food bank use affects them. While participants were largely thankful for the services and mostly spoke positively of the volunteers and staff, they experienced feelings of perceived stigma, encountered expected gratitude, were confronted with lack of choice and found that the experience of using the services could have a negative impact on their identity, self-esteem and dignity.

Food bank services go some way to alleviating immediate hunger for those who use the services. Participants spoke positively of some aspects of the service, but along with these positives, there were also elements of the service that had the potential to negatively impact the participants.

From the studies analysed in this review, it is clear that a proportion of participants reported a perception of stigma as part of their food bank experience. McNeill (2011) differentiated between participants’ experiences of ‘internal’ and ‘external’ stigma. In their study on the sufferers’ perceptions of epilepsy and its impact on their lives, Scambler and Hopkins (1986) make an important distinction between what is termed ‘enacted’ and ‘felt’ stigma. Enacted stigma refers to actual occurrences of discrimination or judgement against people, whereas felt stigma is a much more complicated issue and encompasses not only the fear of encountering enacted stigma, but also includes the internal feelings of shame experienced. Participants in these studies were certainly experiencing felt stigma, as most of the comments centred around participant’s fear of being stigmatised, and their own perception of the stigma that surrounded their situation. Scambler and Hopkins (1986) found that felt stigma can be more powerful than enacted stigma, and can cause unhappiness, anxiety and self-doubt amongst those experiencing it. Anxiety resulting from felt stigma appears to be a very real barrier to people accessing food banks, and can also be expected to exert a negative impact on psycho-social health over and above the impact on physical health caused by poor nutrition.

There was discussion about participants feeling obliged to show gratitude towards the volunteers and the service. Both van der Horst et al. (2014) and Hicks-Stratton (2004) explored this theme of ‘expected gratitude’, stating that participants often only expressed gratitude because they knew it
was expected of them, even if they were dissatisfied with the service\textsuperscript{24, 31}. The work of Marcel Mauss (1990 [1950]) on the concept of the ‘gift’\textsuperscript{39} provides an interesting lens for analysis of this review, because essentially the provision of food from food bank is a ‘gift’ to the users. Mauss’ states that a gift is received “with a burden attached”\textsuperscript{(p41)} and that there is an obligation to reciprocate once accepting the gift\textsuperscript{39}. He further states that “to accept without giving in return… is to become client and servant, to become small”\textsuperscript{(p74)}. Mauss’ theory of the ‘gift’ has been applied to food banks by Vlaholias’ et al. (2015) where she concludes that food banks may be perpetuating and in some cases exacerbating inequality through this concept of the unreciprocated gift\textsuperscript{40}. For people using the food banks, they are often in vulnerable situations where they have no other option but to seek and accept food charity from food banks, therefore accepting a gift that they have no means or intention of returning, which can be damaging to one’s self-esteem and dignity. Mauss also states that to give “is to show one’s superiority, to be more, to be higher in rank”\textsuperscript{(p74)}, which could explain the presence of expected gratitude felt by the users. This theory may also provide an explanation for the strong desire of some participants to volunteer at the food banks once accessing the services; this was a way they felt they could reciprocate the gift of food that they had been given.

All but one of the food banks studied offered pre-packaged hampers to individuals with minimal, if any, choice of the food items they received. Lack of food choice resulted in individuals receiving food items they did not usually eat, did not know how to prepare or food that was of sub-optimal quality\textsuperscript{21, 28-30, 33, 34}. Consequently, going to the food bank and receiving this unsuitable food was found to lead to disappointment, which when compounded by other factors of their vulnerable situations could have a negative impact on identity, self-esteem, reputation and dignity\textsuperscript{23, 24, 31}. Mann (1998) and Jacobson (2009) assert that violations of dignity have the ability to negatively impact the physical, mental and social-wellbeing of individuals\textsuperscript{41, 42}. Consistent violation of dignity, by providing unsuitable food to individuals, has the potential to compound and affect the health and wellbeing of the individuals using this service.

The studies in this review are of mixed origin, and include published journal articles, theses and organisation reports. Assessment against the CASP guidelines indicated some studies were lacking in quality, but were included regardless as this area of study is under-researched and limited studies were available. Some studies did not reveal how participants were recruited\textsuperscript{32, 35} or how data were analysed\textsuperscript{25, 26, 32, 35}, which raises questions about the appropriateness and credibility of their results.
Eight of the studies included in this review used multiple qualitative methods, allowing comparison between data sets and adding strength to their results. Another strength of the literature is the common categories that emerged across the studies, which verify the findings and provide a consistent perspective on user perceptions of food banks. The studies included in the review were all conducted in high-income countries with commonality in the way the food banks were run, and similarity in the people accessing the services. As the included studies spanned across 16 years, they provided insight and information on more than a decade of user perceptions. Interestingly there is consistency in user perspectives across time and countries.

Implications for research

Despite best efforts, these studies demonstrate that food banks are not meeting users’ needs when compared with the Committee on World Food Security’s definition of food security, which states that people should have access to sufficient, safe and nutritious foods that meet their specific dietary needs and food preferences. Studies consistently reported limited food choice and poor food quality, along with shame, stigma, humiliation and embarrassment associated with food bank use. The poor food quality and limited food choices clearly have an impact on the way users experience food banks. However, even if food banks were providing nutritionally suitable food and meeting users’ needs according to this definition of food security, it would be likely that they would still experience some of the negative feelings associated with food bank use such as shame and stigma. The poor food quality and limited choices acts to compound these psychosocial issues. These findings raise questions about food banks being a widespread model and the dominant response to alleviating food insecurity for vulnerable people. Furthermore, this paper provides valuable information for re-orienting and improving the service delivery of food banks, in order to address users’ dissatisfaction of particular aspects of the current model.

Conclusion

This review indicates that for many, food banks are seen and indeed used as a last resort. Perceived dependence on them is often disliked, and for some can lead to feelings of embarrassment, shame, humiliation and perceived stigma. Most participants valued the presence of food bank, and spoke positively about volunteers, and the social support sometimes provided by the food banks and other recipients of the service. Across these studies there was a dislike of the food provided, often said to be old, inappropriate and/or inedible. Worryingly, this is at a time when the food bank industry is expanding, significantly in some regions, due in no small part to continuing State reliance upon their services. While respondents appreciated these services, many wish to move away from
reliance upon them, indicating that these measures are simply ‘band-aids’ that do little to challenge or shift the structural forces that created the food insecurity that brought them to the food bank’s door. This review suggests that provision of food through food banks would benefit from scrutiny with respect to meeting the social and psychological needs of people who are food insecure.
